

Practical support, when plans change

Alexa+ primary track. Created by Shivam Gupta.

The coordination problem

When a helper cancels, the family coordinator has to find a feasible replacement and confirm that someone agreed. KindHandoff makes the affected commitments, pending offers, and next step visible.

One afternoon, two commitments to recover

Fictional demonstration household. The library ride depends on a packed bag.

Helper	Known constraint	Planner proposal
Maya	Unavailable all afternoon	Replace both commitments
Jo	Home access 14:00-15:00 Cannot drive	Pack library bag 14:30-14:45
Dev	Available from 14:45 Can drive	Give the ride 15:00-16:00

What each commitment means

Offered: the named helper has yet to accept. **Accepted:** that helper has taken responsibility. **Ready:** prerequisites allow the task to start.

Dev accepts his ride, but it waits for Jo to record the bag as packed. A handoff acknowledgment also records the specific plan version read.

The system behind the handoff

The deterministic web language simulator makes real HTTP calls to the MCP server. It uses SDK 1.30.0, specification 2025-11-25, and Web Standard Streamable HTTP. The **@kindhandoff/guard** library handles state transitions, coverage, and ranking. App code owns dependency readiness and versioned acknowledgments. D1 stores household-scoped data and checks the version before writing, so a stale plan cannot silently overwrite a newer one.

Owner sign-in and one-time helper invitations establish identity. The prototype covers practical support. Live Alexa+ onboarding and household validation remain next steps.

Business case and validation

A focused first customer

A working adult coordinates recurring practical support for a parent across several helpers. The key adoption test is whether those helpers accept and update their own commitments.

\$12

per household / month

Pricing hypothesis

Every helper included

Test willingness to pay after real use. No interviews, paying customers, or revenue are claimed.

The competition is real

Caring Village offers shared tasks and AI assistance. Family CareRelay describes confirmed voice entries and handoff summaries. KindHandoff focuses on constraint-based recovery, helper acceptance, and dependencies. Published features overlap; exclusivity remains unproven.

A pilot designed to test the promise

10 planned interviews. Coordinators, helpers, and adults receiving support.

5 planned households. A four-week pilot following a baseline diary.

Primary measure: time from a cancellation to an accepted feasible replacement. Also measure coordinator follow-up effort, repeated helper participation, and voluntary paid continuation. These are planned measures, with no results yet.

Cost discipline

Modelled Workers/D1 cost: \$5/month at 1,000 households, assuming 40 API requests per household per day, 10 ms CPU per request, and 2 MB per household. This unmeasured scenario excludes managed hosting, authentication, support, and optional model costs. The core planner requires no paid model call.

Demo and next steps

Record the public video, run the household pilot, and pursue live Alexa+ onboarding. The additional Open Source contribution is [@kindhandoff/guard](#) under MIT.
